Motivation

- High wealth inequality and increased public spending needs have sparked a debate over the introduction of a wealth tax.
- Taxing wealth may induce behavioral responses that shape the trade-off between equity and efficiency.
- Questions:
  1. How much tax revenue does a wealth tax generate?
  2. How are equity and efficiency affected when the additional revenue from a wealth tax is used to reduce other taxes?

The Importance of Entrepreneurs

- Entrepreneurs are highly concentrated at the top of the income and wealth distribution (Smith et al. 2019).
- Highly productive but less wealthy entrepreneurs may have limited access to external credit to finance their investments.
- Guvenen et al. (QJE, 2023): It can be efficient to tax wealth rather than capital income because it
  - shifts the burden away from productive entrepreneurs,
  - alleviates financial constraints,
  - reallocates capital towards more productive uses.

The Importance of Business Legal Form

- Entrepreneurs may select from various legal forms of business organization, each characterized by distinct
  - tax treatments
  - and legal restrictions on access to external credit.
- The choice of legal form shapes both
  - net returns to entrepreneurial investment
  - and the severity of financial constraints.

share of income legal forms

What We Do

- Explore how entrepreneurs' legal form choice affects the aggregate and distributional impact of taxing wealth.

- Dynamic general equilibrium model: heterogeneous agents decide on labor, investment, and occupation: worker vs. entrepreneur.

- Entrepreneurs choose the legal form of business organization:
  1. Pass-through business: income is taxed as ordinary personal income.
  2. C-corporation:
     - Double taxation: corporate and dividend (qualified income) taxes.
     - Better access to external credit.
     - Operating costs.

What We Do

- Calibrate the model to the US economy
- Quantify the impact of a flat wealth tax on
  - tax revenue, aggregate outcomes, and welfare
  - equity and efficiency under fiscal neutrality:
    - corporate tax
    - personal income tax on ordinary and qualified incomes

Main Findings

1. The impact of wealth taxation is critically shaped by the interaction of legal form choice and financial frictions.

2. On top of the current tax system, a flat wealth tax
   - generates substantial revenue,
   - but reduces the share of C-corporations,
   - tightens credit constraints,
   - creates strong distortions in aggregate outcomes,
   - raises wealth inequality,
   - reduces aggregate welfare.

Main Findings

3. Impact of a flat wealth tax under fiscal neutrality:
   - Output increases if the corporate tax is reduced, but aggregate welfare decreases.
   - Output decreases if income tax is reduced, but aggregate welfare increases.
   - In both cases, wealth inequality increases.

Related Literature

- Wealth tax in macroeconomic models:
  Guvenen, Kambourov, Kuruscu, Ocampo and Chen (2023); Guvenen, Kambourov, Kuruscu and Ocampo (2024); Boar and Midrigan (2022, 2023)

- Legal forms of business organization in macroeconomics:
  Chen, Qi, and Shlagenhauf (2018); Smith, Yagan, Zidar and Zwick (2019); Dyrda and Pugsley (2023, 2024); Di Nola, Kocharkov, Scholl, Tkhir and Wang (2025)

- Our contribution:
  Assess the aggregate and distributional effects of a flat wealth tax, accounting for induced reallocation across occupations and legal forms.

Model

- Time is discrete $t = 0, 1, \ldots$
- Endowment:
  - one unit of time,
  - working ability ε, entrepreneurial ability θ
  - abilities follow a Markov process: $\Gamma(\varepsilon', \theta' | \varepsilon, \theta)$.
- Preferences over consumption and labor: $U(c, \ell)$.
- Assets a, savings a'.
- Taxes:
  - Personal income tax $T(y_\ell, y_d)$ on "ordinary income" y_ℓ and "qualified income" y_d.
  - Social security tax: τ_s.
  - Corporate tax: τ_c.
  - Wealth tax: τ_a.

\end{aligned}$$

Retirees

$$V^R(a) = \max_{c,a'} \left\{ u(c) + \beta(1-\rho_D) V^R(a') + \beta\rho_D \mathbb{E}_{\varepsilon',\theta'} \left[\mathcal{V}(a', \varepsilon', \theta') \right] \right\}$$

subject to

$$\begin{aligned} c + a' &= b\bar{y}_l + ra - T(b\bar{y}_l, ra) + (1-\tau_a)a, \\ a' &\geqslant 0 \end{aligned}$$

Non-Entrepreneurial Sector and Government

- Large non-entrepreneurial sector:

$$F(K^{NE}, N^{NE}) = \left(K^{NE}\right)^{\alpha} \left(N^{NE}\right)^{1-\alpha}$$

- Competitive factor pricing holds:

$$r = \alpha \left(\frac{K^{NE}}{N^{NE}}\right)^{\alpha-1} - \delta, \qquad w = (1-\alpha) \left(\frac{K^{NE}}{N^{NE}}\right)^{\alpha}.$$

- The government budget is balanced:

$$G + B = R^{Inc} + R^{Soc.} + R^{Corp} + R^{Wealth}$$

where B is pension payments.

Calibration and Functional Forms

- Calibrate the model to the US economy of 2013.

- Utility:

$$U(c, \ell) = \begin{cases} u(c) - \upsilon(\ell) & \text{for } o = W, \\ u(c) & \text{for } o \in \{EP, EC\} \text{ and } R, \end{cases}$$

with

$$u(c) = \frac{c^{1-\sigma_1}}{1-\sigma_1}, \quad \upsilon(\ell) = \chi \frac{\ell^{1+\sigma_2}}{1+\sigma_2}.$$

- Entrepreneurial production:

$$f(\theta, k, n) = \theta(k^{\gamma} n^{1-\gamma})^{\nu} \quad \text{with } \gamma, \nu \in (0, 1)$$

Qualified Income Is Taxed at Preferential Rates

2013 U.S. Federal Income Tax Brackets

Taxable Income in $	Ordinary Income Tax	Qualified Dividend Tax
$0 - 17,850$	10	0
$17,851 - 72,500$	15	0
$72,501 - 146,400$	25	15
$146,401 - 223,050$	28	15
$223,051 - 398,350$	33	15
$398,351 - 450,000$	35	18.8
$\geqslant 450,001$	39.6	23.8

- Dividends are part of individual income, therefore they are subject to progressive taxation with a preferential rate.
- Tax bracket is determined by the sum of ordinary and dividend income: $y_\ell + y_d$.

Approximated Income Tax Function

- Extended HSV-income tax function (Heathcote et al., 2017):

$$T(y_\ell, y_d) = (y_\ell + y_d) - \Big((1-s)\tau_{l0} + s\tau_{d0}\Big)(y_\ell + y_d)^{1-\tau_1}$$

  with

  - $s = \dfrac{y_d}{y_\ell + y_d}$ is share of qualified income.
  - τ_{l0} and τ_{d0} capture the average tax levels on ordinary and qualified incomes, respectively.
  - τ_1 captures tax progressivity.

- We calibrate the tax function using data from SCF-TAXSIM.

Conclusions

- This paper investigates the aggregate and distributional effects of wealth taxation within a heterogeneous-agent model featuring incomplete markets and occupational and legal form choice.

- Next steps:
  - Quantify the roles of
    1. differential tax treatments and
    2. differential financial constraints and operating costs

    across legal forms in determining the impact of a wealth tax.
  - Progressive wealth taxation.

Share of Income by Source

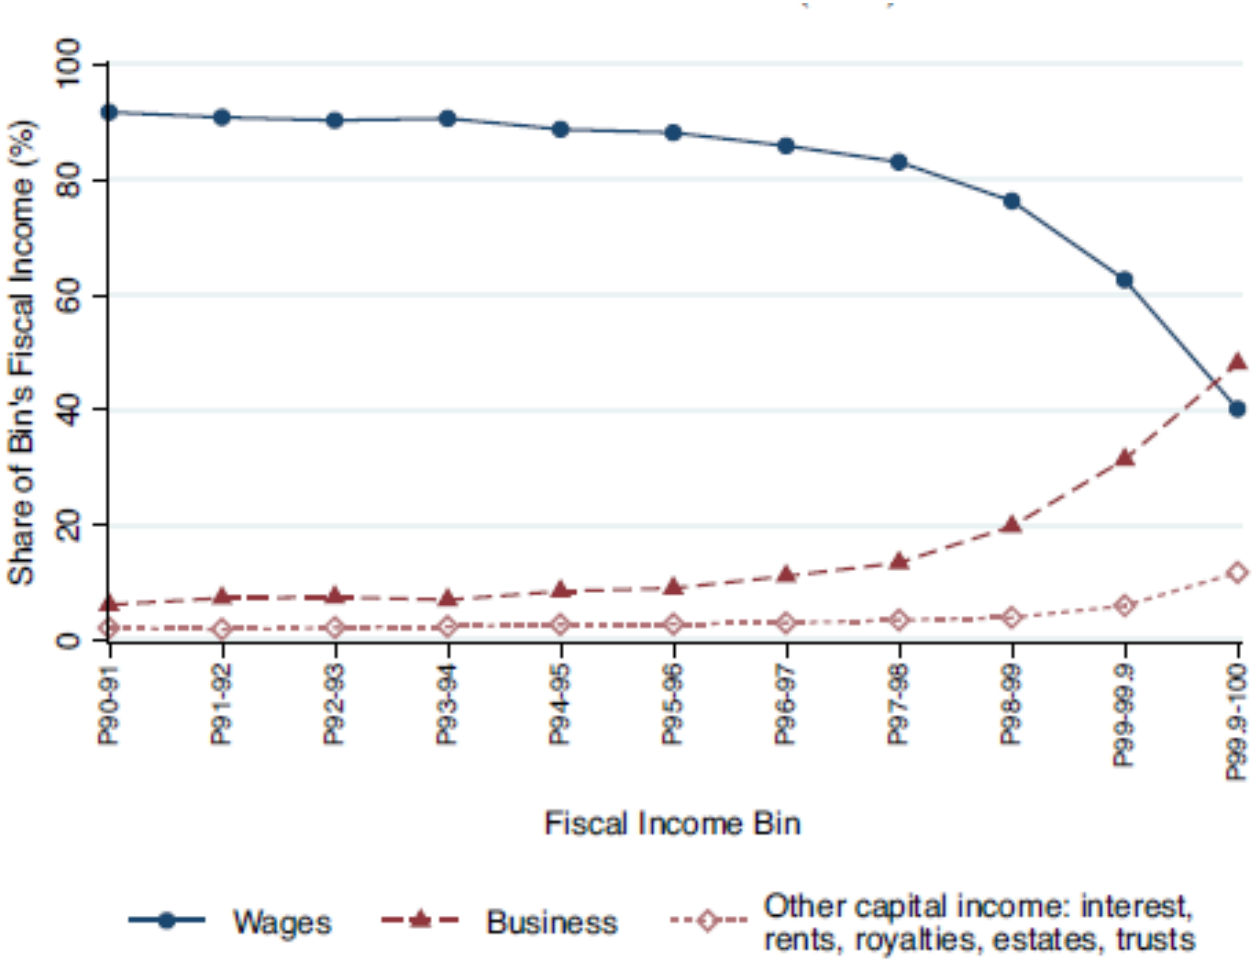

Figure: Smith et al. (2019)

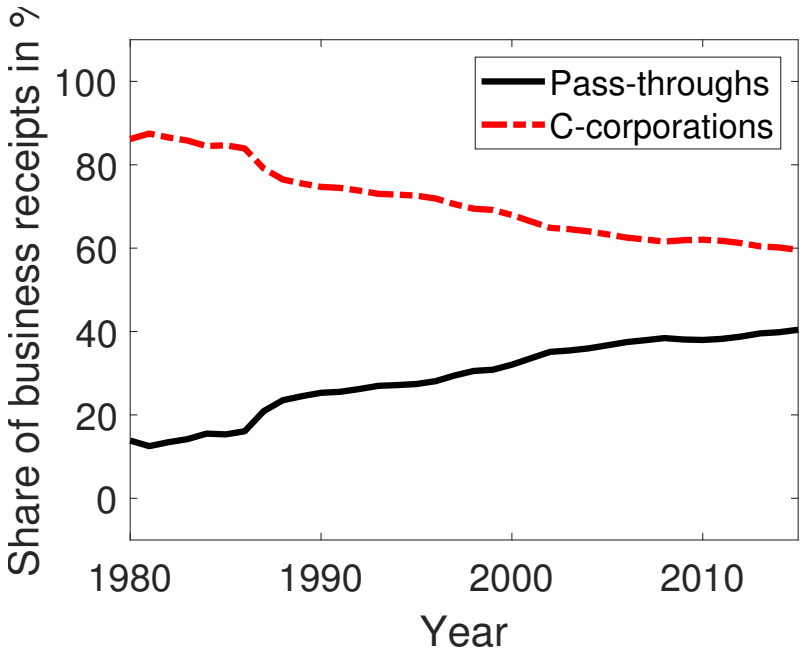
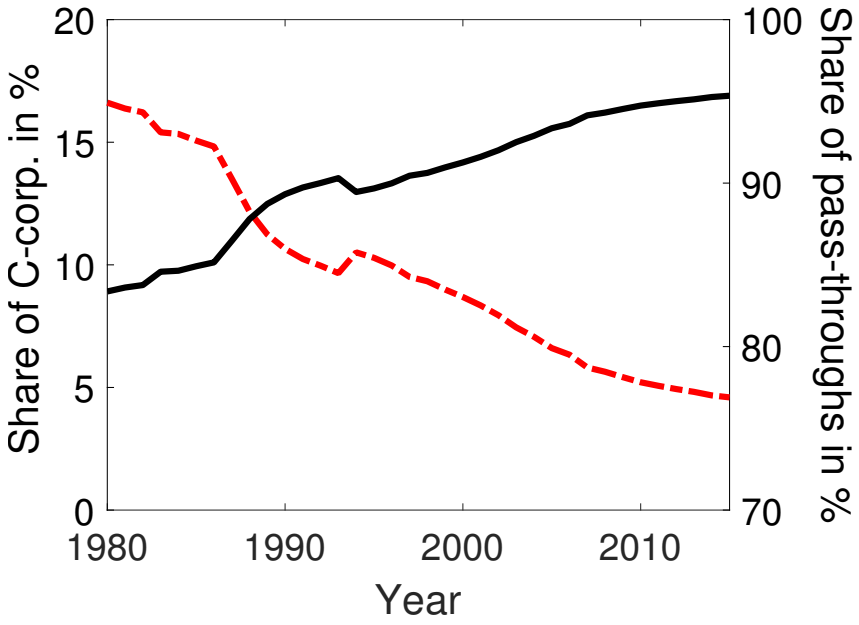
Back

Legal Form of Business Organization





Back

Calibration of the Income Tax Function

- Rewrite:

$$\tilde{T}(y, s) = y - \tau_{I0}\left(1 + s\tilde{\tau}_0\right)y^{1-\tau_1}$$

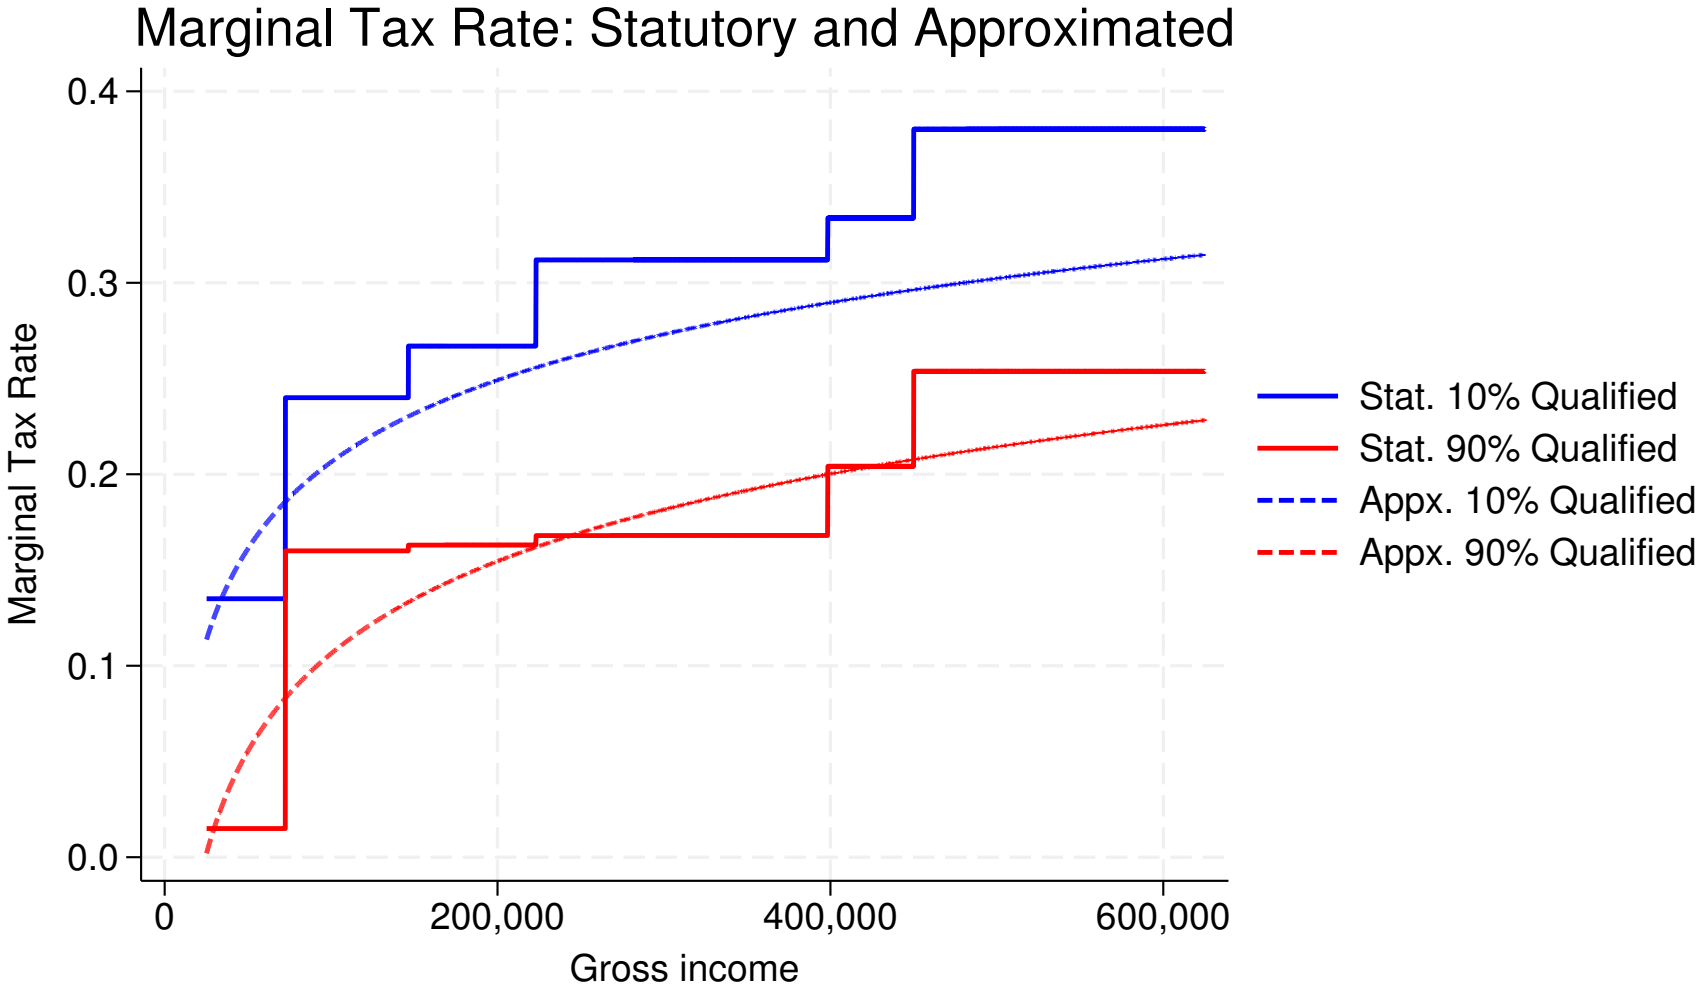
with $y = y_\ell + y_d$ and $\tilde{\tau}_0 \equiv \dfrac{\tau_{d0} - \tau_{I0}}{\tau_{I0}}$

- $\tilde{\tau}_0$ and τ_1 are estimated using SCF by regressing net income on gross income and share of qualified income.

- τ_{I0} is calibrated internally to match G/Y.

Back

Approximated vs. Statutory Tax Function



Note: The approximated tax function is estimated from the data, rather than a fit of the statutory schedule.
